

# Let's Talk About URL State Management

JavaScript Mastery

# What is State Management?

State management in web development refers to how **data is stored and shared across components** of a web application.

It ensures that the application's state (data and UI) remains **consistent** and **synchronized**.

```
import React, { useState } from 'react';

function Counter() {
  const [count, setCount] = useState(0);

  return (
    <div>
      <p>You clicked {count} times</p>
      <button onClick={() => setCount(count + 1)}>
        Click me
      </button>
    </div>
  );
}

export default Counter;
```

# State Management Methods

There are **various ways** to manage the state of your application.

Depending on whether the state needs to be managed on a **local** or **global** level, you may reach for state management tools such as:

- **The useState hook**
- **Context API, or**
- **Redux/Redux Toolkit**

But have you tried storing the state in the **URL?**

# Enter URL State Management

Have you ever visited an **e-commerce** store? Say it's an online store that **sells t-shirts**.

You choose a t-shirt and select a **color**. If you now look at the URL, you might notice **the selected color** there.

<https://vercel.com/acme-mug?color=Black>

In this way, **the state is being stored in the URL** – which we can then retrieve later where needed! 🔥

# useSearchParams()

In Next.js, we can use hooks such as **useSearchParams()** to read the data from the URL.

## useSearchParams

`useSearchParams` is a **Client Component** hook that lets you read the current URL's **query string**.

`useSearchParams` returns a **read-only** version of the `URLSearchParams` [↗](#) interface.

JS app/dashboard/search-bar.js

JavaScript ▾

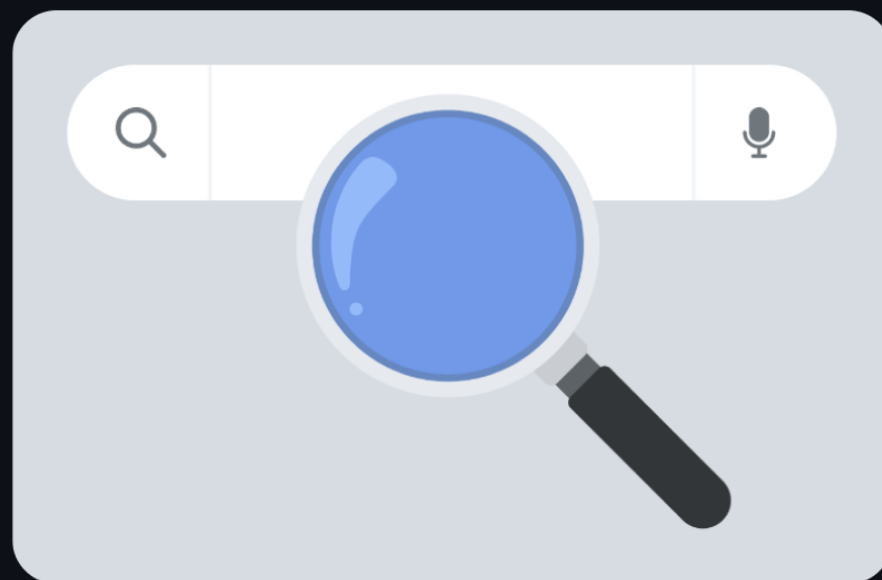

```
1  'use client'
2
3  import { useSearchParams } from 'next/navigation'
4
5  export default function SearchBar() {
6    const searchParams = useSearchParams()
7
8    const search = searchParams.get('search')
9
10   // URL -> `/dashboard?search=my-project`
11   // `search` -> 'my-project'
12   return <>Search: {search}</>
13 }
```

# When can it be used?

URL state management is great for things like:

- **pagination**
- **search boxes**
- **filtering**
- **modal visibility, and**
- **data fetching.**

But it should **NOT** be used when the state has **sensitive information.**

# What are some advantages?

- **Bookmarkability & Easy Sharing** – If you bookmark a page, it will **look the same** when you return to it later. In addition, anyone who clicks on the shared URL **will also see exactly** what the original user was viewing.
- **Native Browser Navigation Support**– Users can navigate through different states of the application using the **back and forward buttons**.
- **Flexibility and Integration** – It **can be combined with other state management solutions** like Redux or Context API in React, allowing developers to leverage the strengths of both approaches.

Have you tried **URL state management** before?

Would you like to use  
it in your next project?
