What is an API Call?

An **API call**, also known as an API request, is the mechanism through which a client application requests or sends data to an API.

An API call includes the **endpoint URL** and the **HTTP method**, as well as any headers, query parameters, or request body data.

The call is received by the **API server**, which processes it and returns a response.

The **response** can include the requested data, confirmation of a successful operation, or an error message if something went wrong.

Thanks for reading!
