# NEW HOOKS IN

REACT 19

PRINCE MEGHANI

01

use() Hook

The use() hook is a part of React's **experimental** API. It allows you to read the value of a resource, such as a **Promise or context**, within your components or custom hooks.

Unlike traditional hooks, use() can be **called within loops and conditional statements**, providing greater flexibility in your code structure.

SWIPE →

useFormStatus() Hook

The useFormStatus() hook gives you **status information of the last form submission**.

It returns an object with properties like **pending, data, method, and action**.

03

useFormState() Hook

The useFormState() hook **creates component state that is updated when a form action is invoked**.

You pass useFormState an existing form action function as well as an initial state, and it **returns a new action that you use in your form**, along with the latest form state.
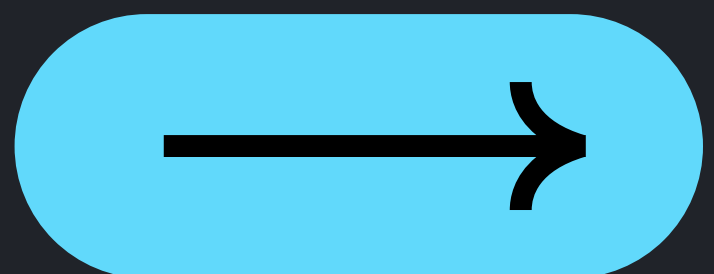

SWIPE

useOptimistic() Hook

The useOptimistic() hook lets you **show a different state while an async action is underway**.

It accepts some state as an argument and **returns a copy of that state that can be different during the duration of an async action** such as a network request.
